Do conditional cash transfers improve the uptake of health interventions in low- and middle-income countries?

Over the past few years, several Latin American countries have introduced programmes that provide monetary transfers to households on the condition that they comply with certain health behaviours. The rationale is that the transfers can potentially increase the use of health services by low-income individuals by providing funds to help overcome some financial barriers to access.

Key messages

- Six studies of conditional cash transfer programmes carried out in low and middle-income countries found an increase in the use of health services and mixed effects on immunisation coverage and health status.

- The capacity of each health system to deal with the increased demand should be considered, particularly in low-income countries where the capacity of health systems may not be sufficient.

- The cost-effectiveness of conditional cash transfer programmes, compared with supply-side strategies and other policy options, has not been evaluated.
Background

In the past decade, some Latin American and African countries have introduced programmes that provide monetary transfers to targeted households on the condition that they comply with a set of behavioural requirements. These requirements are typically linked to attendance at primary care centres for preventive interventions and to educational enrolment for children.

The rationale is that the transfers can potentially increase the use of health services by low-income individuals by providing funds to help overcome some financial barriers to access, such as the costs associated with seeking health care or sending children to school.

Interest in conditional cash transfers has increased and such programmes are being implemented in a number of countries within and beyond Latin America.

About the systematic review underlying this summary

Review objective: To assess the effectiveness of conditional monetary transfers in improving access to and use of health services, as well as improving health outcomes, in low- and middle-income countries

Date of most recent search: April 2006

Limitations: This is a good quality systematic review with only minor limitations.

Summary of findings

Ten articles that reported the results from six studies (four randomised trials, one quasi-randomised evaluation, and one controlled before–after study) were included. Five out of six studies evaluated large-scale conditional cash transfer programmes in Latin America (Mexico, Nicaragua, Colombia, Honduras and Brazil), targeted at disadvantaged households in low-income areas in order to increase school and preventive health examinations attendance. The other study was of a pilot programme in Malawi that tested whether financial incentives would increase the collection of HIV test results.

The mean monetary transfer per household ranged between US $17 and 50 for Latin American studies and was US $1 per individual in the Malawi study. In the case of Mexico, Nicaragua and Brazil households received additional nutrition supplements for children.

⇒ Overall, the evidence suggests that conditional cash transfer programmes can be effective in increasing the use of preventive services and can sometimes improve immunisation coverage and health status.

p: p-value
GRADE: GRADE Working Group grades of evidence (see above and last page)

About the quality of evidence (GRADE)

High: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low: We are very uncertain about the estimate.

<table>
<thead>
<tr>
<th>Findings</th>
<th>Interpretation*</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>APPLICABILITY</strong></td>
<td></td>
</tr>
<tr>
<td>➤ All of the studies were undertaken in low- and middle-income countries, predominantly in Latin America.</td>
<td>➤ Most of the evidence is likely to be applicable in Latin American health systems, although differences in health systems that could impact on the effects of conditional cash transfers still need to be considered. In particular, the capacity of health systems to deal with increased demand needs to be considered. In resource-poor settings where public spending on healthcare is low and access to effective interventions limited, expanding the capacity of health services would be necessary for cash transfers to result in improved use of health services.</td>
</tr>
<tr>
<td>➤ Components of the evaluated programmes other than the cash transfers may have impacted on the results. For instance, health status and anthropometric measures could have been influenced by nutritional supplements provided to children in these studies; better diet resulting from the increased available revenue of households; or the benefits of mothers attending health education meetings.</td>
<td>➤ It is difficult to disentangle the relative importance of different components of the programmes that included more than cash transfers. The effects of non-cash components could be especially relevant in some LMICs.</td>
</tr>
<tr>
<td><strong>EQUITY</strong></td>
<td></td>
</tr>
<tr>
<td>➤ In Nicaragua, increases in household expenditures were the greatest for the poorest group as was the uptake of preventive services for infants. On the other hand, nutritional benefits in Mexico were greater for children whose mother had more than five years of schooling, which could suggest that these programmes do not achieve perfectly their ambition of &quot;levelling the playing field&quot;.</td>
<td>➤ Children from disadvantaged environments, at household and community levels, seem to gain greater benefits from the programmes than those from more advantaged environments. However, it may be more difficult and costly for people living in rural and other underserved areas to have access to the specific health services targeted by cash transfers. Therefore, if an adjustment is not incorporated into the transfers, those recipients would benefit less than those with better access to health services.</td>
</tr>
<tr>
<td><strong>ECONOMIC CONSIDERATIONS</strong></td>
<td></td>
</tr>
<tr>
<td>➤ Conditional cash transfer programmes may require significant flows of money.</td>
<td>➤ It is not possible, especially for resource-poor settings, to establish which policy options would be the most efficient in improving access to and use of health services for targeted populations. For example, the removal of users fees for using health facilities is an alternative policy option to improve access and utilisation in some contexts.</td>
</tr>
<tr>
<td><strong>MONITORING &amp; EVALUATION</strong></td>
<td></td>
</tr>
<tr>
<td>➤ The cost-effectiveness of conditional cash transfer programmes compared with supply-side interventions (for example, improving the quantity and quality of healthcare services) has not been evaluated.</td>
<td>➤ The cost-effectiveness of conditional cash transfer programmes should be evaluated in low-income settings with more limited health system capacity prior to wide spread implementation in those settings. Attention should be paid to evaluating which components play a critical role (cash versus non-cash transfers); the size of the transfers; and the financial sustainability of such programmes.</td>
</tr>
<tr>
<td>➤ Cash transfers may be either too high or too low to induce the conditional action, resulting in inefficiency.</td>
<td></td>
</tr>

About quality of evidence (GRADE)

The quality of the evidence is a judgement about the extent to which we can be confident that the estimates of effect are correct. These judgements are made using the GRADE system, and are provided for each outcome. The judgements are based on the type of study design (randomised trials versus observational studies), the risk of bias, the consistency of the results across studies, and the precision of the overall estimate across studies. For each outcome, the quality of the evidence is rated as high, moderate, low or very low using the definitions on page 3.
